# LOCAL SEO CRAWL AND REMEDIATION PLAN

Rental Power UAE | Local environment review | 18 October 2026

Audit target: **http://127.0.0.1:8000/**
Purpose: identify crawl, canonical, sitemap, metadata, structured-data, internal-link and content-overlap issues, then sequence fixes for an indexable production site.

## Executive summary

**The site has a solid starting point: public routes render server-side, sitemap-listed posts/products/services/categories returned HTTP 200, key templates have descriptive titles and meta descriptions, and the sampled JSON-LD blocks parse as valid JSON. The main launch concern is URL consistency: most URLs in the page sitemap redirect, and service sitemap URLs can redirect to a URL whose canonical points back to the sitemap URL. Resolve those signals before expanding content or submitting the sitemap.**

| Crawl group | URLs checked | First response | Audit note |
|---|---|---|---|
| Pages sitemap | 73 | 23 x 200; 50 x 301 | 50 sitemap entries redirect to another public URL. |
| Fleet products | 20 | 20 x 200 | Titles, descriptions and one H1 in checked set. |
| Services | 17 | 17 x 200 | Canonical and route target conflict across service family. |
| Posts | 16 | 16 x 200 | Distinct post titles and descriptions; canonical self URLs. |
| Categories | 3 | 3 x 200 | /category/blog renders blog index and canonicalizes to /blog. |
| Total sitemap URLs | 129 | 79 x 200; 50 x 301 | No sitemap-listed 404/5xx first response observed. |

### What this audit can and cannot establish

This is a local crawl and code/data review. It cannot guarantee rankings or reproduce Googlebot, the production host, Search Console canonical selection, live Core Web Vitals, backlinks, or keyword demand. Production checks must confirm APP_URL, HTTPS redirects, canonicals, robots.txt and sitemap URLs agree on the chosen hostname.

# Priority findings

## P0 | Make public URLs, canonicals and sitemap entries agree

The pages sitemap contains 73 URLs; 50 return a 301 on first request (68%). Examples include legacy /products/... and flat-slug paths that redirect to /fleet/..., plus nested /services/{section}/{slug} paths that redirect to /service/{slug}. Redirecting URLs should not be submitted as canonical sitemap entries.

A stronger conflict appears on services: **/services/generator/rental-generator-in-uae** returns 301 to **/service/rental-generator-in-uae**, but the destination currently declares a canonical pointing back to the nested /services/... URL. The same pattern is present across cooling and buy/sell service URLs. This creates conflicting canonical and redirect signals.

**Action: choose one stable route per service and fleet item. Make internal links, self-referencing canonicals and sitemap locations use that final 200 URL. Redirect aliases directly to it. Never canonicalize a URL that itself redirects.**

## P1 | Remove duplicate legacy CMS URLs from the indexable set

The database contains 60 published CMS pages in addition to dedicated Product and Service records. Numerous CMS page titles repeat across legacy slug families; for example, generator product pages exist as both products/{slug} and {slug} page records while the dedicated fleet route is /fleet/{slug}. Several sitemap entries therefore point to redirects for content already represented by product/service sitemaps. This is a URL/content overlap issue; it does not by itself prove Google ranking cannibalization.

Action: map each legacy record to its intended current page; then redirect old paths and exclude them from sitemaps. Retain an old URL only if it has a distinct search intent and unique, useful content. Do not delete CMS records until redirect and backlink needs are understood.

## P1 | Confirm the production canonical host

The local homepage declares http://127.0.0.1:8000 as canonical, while sitemap URLs use https://rentalpower.ae. This difference may be expected locally, but production must emit only the final HTTPS hostname. Verify APP_URL and proxy/HTTPS handling on production and inspect representative pages in Search Console URL Inspection.

# Sitemap, metadata and content overlap

## Sitemap publication and discovery

• All five sitemap child endpoints and the sitemap index returned XML/HTTP 200. The child sets include 73 page URLs, 20 products, 17 services, 16 posts and 3 categories. The 20 product, 17 service, 16 post and 3 category URLs checked returned HTTP 200. The page sitemap returned 23 x 200 and 50 x 301.

• robots.txt lists the combined sitemap.xml, sitemap-index.xml and all five child sitemaps. Since the index already references the five children, publish one sitemap-index URL in robots.txt and submit that index in Search Console.

• A category with slug blog produces /category/blog, but that route renders the blog listing and declares /blog as canonical. Remove this alias from the category sitemap or permanently redirect it to /blog.

• The page sitemap includes CMS records that duplicate dedicated fleet/service records, including old /products/..., nested /services/... and flat slugs. Generate sitemap entries only from intended canonical 200 pages.

## Images and asset URLs

A sitemap image URL was emitted as **/storage/storage/media/used-con.jpg** and returns 404; the actual asset at **/storage/media/used-con.jpg** returns 200. The page sitemap builder prepends storage/ to stored image values; normalize values that already include the storage prefix. Then crawl every image:loc and require 200.

## Titles, descriptions and keywords

• Checked public pages have titles and descriptions. One page, /services/generator, has two H1 headings; reduce it to one. Observed description lengths ranged from 73 to 213 characters; refine unique snippets. Google may choose a different snippet.

• The CMS pages table has no meta_keywords value on 60/60 records; meta keywords are also absent on 1 post and 9 products. Google Search ignores the meta-keywords tag. Focus on visible content and accurate page-specific titles/descriptions instead.

• Potential query overlap: fleet capacity pages (50-1250 kVA), broad generator rental services, brand pages and city pages all mention generator hire. Assign a primary intent and target URL for each cluster, then differentiate copy and anchors. Confirm actual cannibalization using Search Console query-to-page data before merging.

# Internal links and structured data

## Internal linking

The homepage exposes crawlable links into fleet capacities, services, locations and recent articles; the footer links to service, fleet and regional sections. This is a useful hub. URL-level inspection does not prove every published page is reachable contextually, so run a full internal-link graph after URL consolidation.

• For each post, add a contextual link to its closest service or fleet page and to one related guide; add reciprocal links from service/product pages to genuinely useful supporting guides.

• Use descriptive, varied anchors and HTML anchors with href. Keep breadcrumbs and parent/category links consistent with the final canonical URL.

• Prioritize links from home, fleet and service index pages to commercial pages. Check every intended indexable URL has at least one internal link and no links point to redirected aliases.

## Structured data

JSON-LD syntax parsed successfully on seven representative templates: homepage, service, product, post, category, location and about (23 scripts total, 0 JSON parse failures). Types included WebSite, HomeAndConstructionBusiness, Service, Product, BlogPosting, CollectionPage, LocalBusiness, BreadcrumbList and FAQPage. This verifies JSON syntax on samples only; it does not establish Google feature eligibility or correctness on all 129 URLs.

• Review global business data with the owner: exact address, postal code, hours, accepted payment methods, price range, coverage and social profiles must be real and visible. Correct or remove unsupported values; the current template hardcodes a generic address and postal code.

• Use one consistent Organization/LocalBusiness entity and identifier across templates. Check Product, Service, Article and Breadcrumb data describe visible page content and match canonical URLs.

• Validate production pages with Rich Results Test and Search Console after publishing. Valid markup can make a page eligible for rich results but does not guarantee display.

## Robots and performance

robots.txt allows general crawling and disallows admin, authentication and storage/framework paths, which is directionally appropriate. Confirm these rules on production and ensure no public content URL is blocked or marked noindex. Mobile performance and Core Web Vitals were not measured in this local crawl; run Lighthouse/PageSpeed Insights and review Search Console separately.

# Execution plan and acceptance checks

## Phase 1 - URL and sitemap cleanup (first)

• Decide the canonical HTTPS hostname and the single public URL shape for services, products, posts, categories and pages.

• Fix canonical targets so each is a self-canonical 200 page. Make redirect aliases point directly to it, one hop where possible.

• Update navigation, footer, related links and breadcrumbs to use final URLs; remove redirecting and duplicate entries from every sitemap.

• Fix the doubled storage/ image path. Keep only one sitemap-index directive in robots.txt and verify every child XML is parseable.

## Phase 2 - content and intent mapping

• Build a URL-to-query map for generator rental, capacity, chiller, packaged AC, brand, location and used-equipment topics.

• Use Search Console queries and page performance to confirm whether pages compete. Consolidate thin duplicates; retain pages with distinct intent and useful unique evidence.

• Improve articles with practical expertise: sizing examples, assumptions, UAE conditions, author/reviewer details and original diagrams or field evidence.

• Add relevant contextual internal links from articles to commercial pages and back to supporting guides.

## Phase 3 - production validation and monitoring

• Crawl production and confirm 200 status for each sitemap URL, one canonical hostname/protocol, self canonicals, no noindex and no internal links to redirects.

• Submit the sitemap index in Search Console. Inspect the homepage, one page from each template and URLs reported as duplicates, crawled-not-indexed or excluded.

• Run Rich Results Test and PageSpeed Insights on representative production templates; monitor indexing, query/page overlap and Core Web Vitals.

## Definition of done

**Every sitemap URL returns 200, is indexable, has a self-canonical matching its sitemap URL, and is reachable by at least one relevant internal link. Redirect aliases are absent from sitemaps and internal navigation; sitemap image URLs return 200; structured data is valid and factually supported; Search Console has no unresolved canonical, sitemap or crawl errors for the submitted set.**

Audit boundary: sitemap-listed public URLs and local Laravel route/data sources were reviewed on 18 Oct 2026. Google Search Console, production crawl, backlinks, ranking positions, query-level cannibalization, Lighthouse and Search Console Core Web Vitals are outside this local audit. No ranking position is guaranteed.
